Figure S. 1 DC magnetic susceptibility of a polycrystalline sample of 1, measured in a 1,000 Oe external field. Experimental points are shown in red and simulations using a spin Hamiltonian with the parameters recorded in the HFEPR, $|\mathrm{D}|=19.6 \mathrm{~cm}^{-1}$ and $|\mathrm{E}|=2.02 \mathrm{~cm}^{-1}$. The black line indicates a positive D value and the blue line indicates a negative $D$ value. Simulation was performed using the EasySpin software package. ${ }^{1}$

## S. 2 High Field Electron Paramagnetic Resonance (HFEPR)

HFEPR spectra were recorded at the National High Magnetic Field Laboratory (NHMFL, Tallahassee, FL) using the homodyne transmission spectrometer equipped with a $15 / 17 \mathrm{~T}$ superconducting magnet. ${ }^{2}$ Measurements were carried out on a powder sample of $1(\sim 30 \mathrm{mg})$ ground up with eicosane wax. The sample was packed into a Teflon sample holder. Spectra were recorded at 4.5 K and 10 K at multiple frequencies from 203 to 634 GHz in a 0 to 14.5 T field range and the spectrum at 10 K and 203.2 GHz is given in Figure S.2. The 2D magnetic field versus frequency simulations in Figure 3 and the spectral simulations in Figures 2 and S.2, were generated using the following spin $\mathrm{S}=1$ Hamiltonian: $\widehat{H}=D \hat{S}_{z}^{2}+E\left(\hat{S}_{x}^{2}-\hat{S}_{y}^{2}\right)+g \mu_{B} \vec{B} \cdot \hat{S}$, where the first two terms represent the $2^{\text {nd }}$ order axial and rhombic zero field splitting interactions, parameterized respectively by $D$ and $E$, and the final term represents the Zeeman interaction: $\hat{S}$ is the spin operator and $\hat{S}_{i}(i=x, y, z)$ its components, $\vec{B}$ is the applied magnetic field vector, $\overleftrightarrow{g}$ the Lande $g$-factor (assumed to be direction independent for this analysis), and $\mu_{B}$ the Bohr magneton.

Figure S.2 HFEPR spectrum of 1 recorded at 10 K and 203.2 GHz (black trace). The high-amplitude signal from a $\mathrm{Mn}(I I)$ impurity at $\mathrm{g}=2.00$ has been removed from the experimental spectrum for clarity. The resonance at 1.35 T (*) cannot be attributed to the $S=1$ state and its origin remains unknown. The signal at 6.25 T originates from the probe. The two coloured traces are simulations assuming a powder distribution of the microcrystallites, using spin Hamiltonian parameters as in the text, but different sign of $D$. Red trace represents positive $D$; blue trace - negative $D$. By comparing the experiment with simulations we can unequivocally determine the sign of $D$ as positive.

## S. 3 Single Crystal X-Ray Diffraction of 1, 2, 2•0.5EtOH, 3•0.5EtOH, 4

Single crystal X-ray diffraction was carried out on suitable single crystals using an Oxford Supernova diffractometer (Oxford Instruments, Oxford, United Kingdom). Datasets were measured using monochromatic Cu -Ka radiation for 1, 2, 4 and $\mathbf{3 \cdot 0 . 5} \mathbf{E t O H}$ and monochromatic Mo-Ka radiation for 2.0.5EtOH and corrected for absorption. The temperature was controlled with an Oxford Cryosystem instrument. A complete dataset was collected, assuming that the Friedel pairs are not equivalent. Analytical absorption correction based on the shape of the crystals was performed. ${ }^{3}$ All structures were solved by dual-space methods (SHELXT) ${ }^{3}$ and refined by full matrix least-squares on $\mathrm{F}^{2}$ for all data using SHELXL-2016. ${ }^{4}$ The hydrogen atoms attached to nitrogen were located in the difference Fourier map and allowed to refine freely. All other hydrogen atoms were added at calculated positions and refined using a riding model. Their isotropic displacement parameters were fixed to 1.2 times the equivalent one of the parent atom. Anisotropic displacement parameters were used for all nonhydrogen atoms. Crystallographic details for all compounds are summarised in Table S.2. Crystallographic data for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication numbers CCDC-1921981 (1, 100 K), CCDC-1921978 (2, 100 K), CCDC-1921977 (2•0.5EtOH, 100 K), CCDC-1921979 (3•0.5EtOH, 100 K ), CCDC-1921980 (4, 100 K ).

## S. 4 X-Ray Crystal Structure of 2, 2•0.5EtOH, 3•0.5EtOH, 4

Figure S. 3 Structure of 2 recorded at 100 K. Thermal ellipsoids are drawn at $50 \%$ atomic probability. Hydrogen atoms have been omitted for clarity.

Figure S. 4 Structure of $\mathbf{2 \cdot 0 . 5 E t O H}$ recorded at 100 K . Thermal ellipsoids are drawn at $50 \%$ atomic probability. Hydrogen atoms have been omitted for clarity, except for those on the solvent molecule.

Figure S. 5 Structure of $\mathbf{3 \cdot 0 . 5 E t O H}$ recorded at 100 K . Thermal ellipsoids are drawn at $50 \%$ atomic probability. Hydrogen atoms have been omitted for clarity, except for those on the solvent molecule.

Figure S. 6 Structure of 4 recorded at 100 K . Thermal ellipsoids are drawn at 50\% atomic probability. Hydrogen atoms have been omitted for clarity, except for those on the solvent molecule.

## S. 5 Crystallographic Data for 1, 2, 2•0.5EtOH, 3•0.5EtOH and 4

## S. 6 Distortion Parameters for 1, 2, 2•0.5EtOH, 3•0.5EtOH, 4

Octahedral distortion parameters were determined with the use of: OctaDist - A program for determining the structural distortion of the octahedral complexes. (https://octadist.github.io)

The distortion parameter $\Theta$ is a measure of the deviation of the metal centre geometry from perfect octahedron $\left(\mathrm{O}_{\mathrm{h}}\right)$ to trigonal prismatic $\left(\mathrm{D}_{3 \mathrm{~h}}\right)$. It is calculated by the sum of the deviation of the 24 unique ligand-metal-ligand angles $(\theta)$ from $60^{\circ}$ as per Equation S.1:

$$
\Theta=\sum_{i=1}^{24}\left|60-\theta_{i}\right|
$$

The more distorted the octahedron the higher the $\Theta$ value, therefore as the HS state is expected to be more distorted, a higher the value of $\Theta$ should be observed in the HS state, and consequently a lower value of $\Theta$ in the LS state. ${ }^{5}$

The distortion parameter $\Sigma$ is a measure of the sum of the deviation from $90^{\circ}$ of the 12 cis angles $(\phi)$ in the metal coordination sphere, given by Equation S.2:

$$
\Sigma=\sum_{i=1}^{12}\left|90-\phi_{i}\right|
$$

Similarly, the HS state is expected to be more distorted so the value of $\Sigma$ should be greater for the HS state.

Table S. 5 Distortion parameters $\Sigma$ and $\Theta$ for 1, 2, 2•0.5EtOH, 3•0.5EtOH, 4 .

| Complex | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{2 \cdot 0 . 5 E t O H}$ | $\mathbf{3} \cdot \mathbf{0 . 5 E t O H}$ | $\mathbf{4}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\boldsymbol{\Sigma}\left({ }^{\circ}\right)$ | 35.32 | 30.97 | 71.37 | 71.25 | 31.27 |
| $\boldsymbol{\Theta}\left({ }^{\circ}\right)$ | 97.20 | 97.07 | 238.81 | 239.22 | 88.41 |

The distortion parameters correspond with the expected ranges of literature values for the complexes in the IS and HS state respectively, with the IS $(S=1)$ state expected to have a value of $\Sigma=30^{\circ}$ $50^{\circ}$ and $\Theta=80^{\circ}-100^{\circ}$ and the $\mathrm{HS}(\mathrm{S}=2)$ state expected to have a value of $\Sigma=60^{\circ}-70^{\circ}$ and $\Theta=$ $140^{\circ}-220^{\circ} .{ }^{6}$

## S. 7 Intermolecular Interactions of 1, 2, 2•0.5EtOH, 3•0.5EtOH, 4

${ }^{\dagger}$ Symmetry transformations used to generate equivalent atoms: \#1 $\mathrm{x}-1, \mathrm{y}, \mathrm{z}$
${ }^{\ddagger}$ Symmetry transformations used to generate equivalent atoms: \#1 $-x+1,-y+1,-z+1$
${ }^{\times}$Symmetry transformations used to generate equivalent atoms: \#1 $x, y-1, z$
*Symmetry transformations used to generate equivalent atoms: \#1 -x+1,-y,-z+1

Figure S. 7 1-D Hydrogen bonding network in 1 with ellipsoids drawn at $50 \%$ atomic probability. Hydrogen atoms, except those involved in the hydrogen bonding, have been omitted for clarity.

Figure S. 8 1-D Hydrogen bonding network in 2 with ellipsoids drawn at $50 \%$ atomic probability. Hydrogen atoms, except those involved in the hydrogen bonding, have been omitted for clarity.

Figure S. 9 Hydrogen bonding (b/ue) and $\pi-\pi$ stacking (red) interactions in $2 \cdot 0.5 \mathrm{EtOH}$ with ellipsoids drawn at $50 \%$ atomic probability. Hydrogen atoms, except those involved in the hydrogen bonding, have been omitted for clarity.

Figure S.10 Hydrogen bonding (b/ue) and $\pi-\pi$ stacking (red) interactions in $\mathbf{3 \cdot 0 . 5 E t O H}$ with ellipsoids drawn at $50 \%$ atomic probability. Hydrogen atoms, except those involved in the hydrogen bonding, have been omitted for clarity.

Figure S. 11 1-D Hydrogen bonding network in 4 with ellipsoids drawn at $50 \%$ atomic probability. Hydrogen atoms, except those involved in the hydrogen bonding, have been omitted for clarity.

## S. 8 Infrared Spectra of 1, 2, 2•0.5EtOH, 3, 3•0.5EtOH and 4

Figure S. 12 Infrared spectra for complexes 1 - 4, 2•0.5EtOH and $3 \cdot 0.5 \mathrm{EtOH}$.

## S. 9 UV-Visible Spectra of $1-4,2 \cdot 0.5 \mathrm{EtOH}$ and $3 \cdot 0.5 \mathrm{EtOH}$.

Figure S. 13 UV-Visible spectra from $200 \mathrm{~nm}-800 \mathrm{~nm}$ of $\mathbf{1 - 4 , 2 \cdot 0 . 5 E t O H}$ and $\mathbf{3 \cdot 0 . 5 E t O H}$ in acetonitrile with concentrations indicated on the spectra.

Figure S. 14 UV-Visible spectra from $450 \mathrm{~nm}-800 \mathrm{~nm}$ for $\mathbf{1 - 4 , 2 \cdot 0 . 5 E t O H}$ and $\mathbf{3 \cdot 0 . 5 E t O H}$ with concentrations indicated on the spectra.

## S. 10 Powder X-Ray Diffraction

Powder X-Ray diffraction (PXRD) experiments were carried out using a Bruker D2 Phaser with CuKa radiation $\lambda=1.5418 \AA$. Samples were used as is and measured on a zero-background silicon sample holder. The data was collected in the $2 \Theta$ Range from $5-55^{\circ}$ in $0.01^{\circ}$ increments at room temperature while rotating the sample at one rotation per minute in $\varphi$ direction. Background due to fluorescence was subtracted. Normalised intensity plots of the experimental (top) and simulated (bottom) powder X-ray pattern of the compounds 1, 2, 3•EtOH and 4.

Figure S. 15 PXRD pattern for 1, 2, 3•0.5EtOH and 4.
